ABSTRACT: This paper introduces new block coded 8-PSK modulations with unequal error protection (UEP) capabilities for Rayleigh fading channels. The design of efficient block coded modulations (BCM) over 8-PSK signal sets, for the specific purpose of UEP, over Rayleigh fading channels is considered. UEP is desirable in communications systems where part of the source information is more important, or error sensitive, such as transmission of coded speech and data broadcasting. The proposed block modulation codes are based on the multilevel construction of Imai and Hirakawa [1]. It is shown that the use of binary linear UEP (LUEP) codes [2] as component codes in one or two of the encoding levels provides, in addition to superior UEP capabilities, a higher error performance, at the expense of a very modest reduction in bandwidth efficiency, with respect to conventional multilevel codes. Computer simulation results show that, over a Rayleigh fading channel, a significant improvement in coding gain is obtained by the use of binary LUEP codes as constituent codes in the multilevel construction.

1. INTRODUCTION

Previous work on combining LUEP codes and PSK modulation for fading channels is reported in references [3] and [4]. Hagenauer et al. [3] proposed rate-compatible punctured convolutional codes combined with DQPSK modulation to provide UEP by means of their inherent variable rate structure. In a previous paper [4] we used Gray labeling of a QPSK signal set to map binary LUEP codes of even length onto block modulation codes with UEP capabilities. Seshadri and Sundberg [5] studied the UEP capabilities of the Imai-Hirakawa multilevel construction over Rayleigh fading channels with binary linear codes of length 8 and nonuniform Gray mapped 8-PSK signal sets. In [6] this study was extended to multilevel trellis coded modulation.

The aim of this research work is to design efficient

block coded modulations (BCM) over 8-PSK signal sets for the specific purpose of UEP over Rayleigh fading channels. The proposed block modulation codes are compared with the best known multilevel BCM using conventional linear block codes [5][9] of the same length and same minimum product and symbol distances, over Rayleigh fading channels.

It is well known that over a fading channel, the minimum symbol and product distances are the parameters that dominate the overall error performance [7]. The product distance determines the error performance at low signal-to-noise ratios (SNR), while the symbol distance dominates at moderate to high SNR and is closely related to the Hamming distance of the component codes. Thus it is natural to use binary LUEP codes as component codes in the multilevel construction to obtain good BCM for UEP over fading channels. To illustrate the proposed modulation codes and their performance, two examples are presented. A detailed analysis of the effects of increasing the symbol and product distances in one or more stages of the multilevel construction is a difficult task for Rayleigh fading channels. In this paper, computer simulation results are reported to show that a significant improvement in coding gain is obtained by the use of an LUEP code as constituent code in the multilevel construction. In the computer simulations we assume a flat slow fading channel, with independent Rayleigh distributed fading amplitudes, and perfect frequency and phase synchronization.

2. PRELIMINARIES

Let S represent a uniform unit-energy 8-PSK signal set (see Figure 1). In this paper, natural labeling (i.e., standard mapping by set partitioning) of set S is considered. That is, a label $\ell_k = b_1 + 2b_2 + 4b_3$ represents the signal point $e^{jk\pi/4}$, for $0 \leq k < 8$, where $j = \sqrt{-1}$, and $b_i \in \{0, 1\}$, $1 \leq i \leq 3$. In multilevel

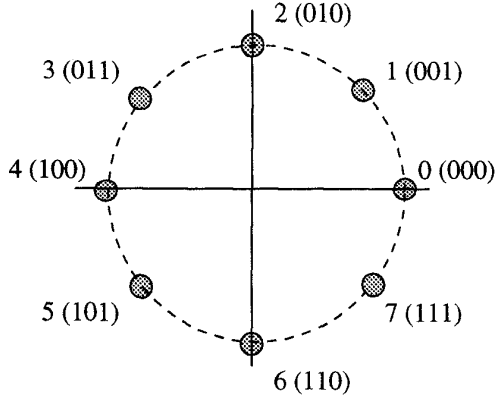

FIGURE 1: An 8-PSK signal constellation with natural labeling

block coded modulation [1], codewords of three linear codes of length n , dimension k_i and minimum distance d_i , denoted C_i , are used to select label bits b_i , for $1 \leq i \leq 3$. The set of resulting sequences of 8-PSK signals is said to be a *block modulation code* Λ of length n and rate (or bandwidth efficiency) $R = (k_1 + k_2 + k_3)/n$ bits/symbol.

Throughout the paper binary LUEP codes are used. For simplicity, only LUEP codes with two levels of error protection are considered. A two-level (n, k) LUEP code is a linear code that it is not spanned by its set of minimum weight vectors [8]. We use $\text{UEP}(n, k)$ to denote such a code and refer to its unequal error protection capabilities as follows: *separation vector* $\bar{s} = (s_1, s_2)$ for the *message space* $\{0, 1\}^{k^{(1)}} \times \{0, 1\}^{k^{(2)}}$, where $k = k^{(1)} + k^{(2)}$. This is to say that codewords in correspondence to $k^{(i)}$ information bits are at a Hamming distance at least s_i , $i = 1, 2$. Without loss of generality, we assume that $s_1 \geq s_2$. Then k_2 is equal to the dimension of the span of the minimum weight codewords of $\text{UEP}(n, k)$. In other words, an information vector of length k bits can be separated into a most significant part of length $k^{(1)}$ bits (the MSB) and a least significant part of length $k^{(2)}$ bits (the LSB).

Figure 2 shows the block diagram of an encoder for the proposed multilevel modulation codes. Conventional (n, k_1, d_1) and (n, k_2, d_2) linear block codes C_1 and C_2 are selected to ensure that the *minimum*

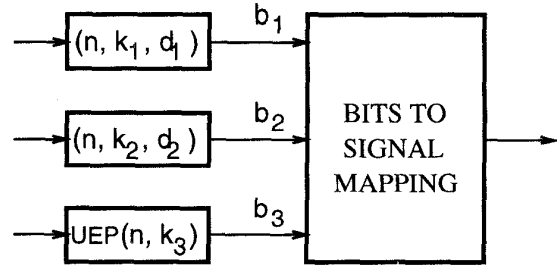

FIGURE 2: An encoder for the proposed multilevel modulation codes for UEP

symbol distance

$$\delta_H \triangleq \min\{d_1, d_2, d_3\},$$

will occur at the second or third encoding levels, so that the *minimum product distance*

$$\Delta_p^2 \triangleq (\delta_k)^{d_k}, \quad k = \min\{i : \delta_H = d_i\},$$

will be greater than 2, where $\delta_1 = 0.586$, $\delta_2 = 2$ and $\delta_3 = 4$. Details on these and other design considerations can be found in [7] and [9]. The proposed multilevel construction uses a $\text{UEP}(n, k_3)$ code C_3 in the third encoding level. In sections 3 and 4, we present example block modulation codes of lengths 8 and 32 to illustrate the proposed construction and its error performance in comparison with other approaches.

In comparing the proposed 8-PSK block modulation codes with conventional ones, the decoding complexity is also used as a measure. For *maximum likelihood soft-decision decoding* (MLSD), the Viterbi algorithm may be used, operating on a trellis diagram T for a modulation code Λ . Much is now known on the structure of trellis diagrams for some classes of linear block codes, notably of Reed-Muller codes (see the list of references in paper [9]). In this paper, we measure the decoding complexity by the number of states of a minimal trellis diagram T_{\min} of Λ . For each encoding stage of the multilevel construction, let 2^{s_i} be the number of states of a minimal trellis diagram for code C_i , $i = 1, 2, 3$. Then the *decoding complexity* of Λ (number of states of T_{\min}) is $2^{s_1} \times 2^{s_2} \times 2^{s_3} = 2^{s_1+s_2+s_3}$. It is also well known [5] that suboptimal *multistage soft-decision decoding* (MSDD) reduces significantly the decoding

complexity at the expense of a very modest reduction in coding gain. With suboptimal MSDD, the decoding complexity of Λ is given by $2^{s_1} + 2^{s_2} + 2^{s_3}$.

3. A LENGTH-8 MULTILEVEL CODE FOR UEP OVER RAYLEIGH FADING CHANNELS

Let C_1 , C_2 and C_3 be (8, 4, 4), (8, 7, 2) and (8, 7, 2) linear codes, respectively. The Imai-Hirakawa multilevel construction results in a block modulation code Λ_1 of length 8, rate $R = 2.25$ bits/symbol, minimum symbol distance $\delta_H = 2$ and minimum product distance $\Delta_p^2 = 4$. This code was analyzed in [5] and its UEP capabilities exhibited through computer simulations.

By letting C_3 be a binary optimal LUEP code, UEP(8, 5), from [10] with separation vector $\bar{s} = (3, 2)$ for the message space $\{0, 1\}^4 \times \{0, 1\}$, a block modulation code Λ_2 is obtained. A (trellis oriented) generator matrix for C_3 is given by

$$G_3 = \begin{pmatrix} 10100101 \\ 01100100 \\ 00110010 \\ 00001110 \\ 00000011 \end{pmatrix},$$

and it can be easily verified that any two codewords of C_3 , in correspondence to information vectors whose first 4 information bits (or, equivalently, the first 4 rows of G_3) differ, are at a Hamming distance of at least 3. Modulation code Λ_2 has length 8, rate $R = 2$ bits/symbol, $\delta_H = 2$ and $\Delta_p^2 = 4$. In addition, 25% of the information bits (the 4 MSB encoded by UEP(8, 5)) have corresponding symbol and product distances equal to 3 and 64, respectively. That is, a subset of the coded sequences, those corresponding to the MSB encoded by the LUEP code, have higher symbol and product distances than the conventional code Λ_1 . It follows that, with *no bandwidth expansion* over uncoded QPSK, *higher error performance* is achieved (See also the simulation results shown in Figure 3).

In terms of decoding complexity, it can be shown that MLSD of Λ_1 requires a trellis diagram of $2^2 \times 2 \times 2 = 2^4$ states, while that of Λ_2 requires $2^2 \times 2 \times 2^2 = 2^5$ states. It follows that the improvement in coding gain and UEP capabilities is attained roughly by doubling the decoding complexity. However, the use of suboptimal MSDD results in comparable decoding complexity for both codes: The

number of states of a minimal trellis diagram for use in MSDD for Λ_1 and Λ_2 is $2^2 + 2 + 2 = 8$ and $2^2 + 2 + 2^2 = 10$, respectively. Therefore with the use of suboptimal multistage decoding, the proposed modulation code of length 8 would require only 25% more decoding complexity than conventional BCM. It is worthwhile noting that in multistage decoding of both Λ_1 and Λ_2 , because the first two codes, (8, 4, 4) and (8, 7, 2) linear codes, are identical, the same reduction of coding gain will be present in the first two decoding stages. The third stage of Λ_2 provides enhanced UEP capabilities.

The multilevel 8-PSK modulation code Λ_2 above is compared with a multilevel code for UEP using conventional linear codes with about the same overall error performance: Time-sharing of (7, 4, 3) and (2, 1, 2) linear codes, which produces a UEP(9, 5) code, denoted $|(7, 4, 3)|(2, 1, 2)|$, is used as C_3 . C_1 and C_2 are (9, 4, 4) and (9, 8, 2) linear codes, respectively. A block modulation code Λ_3 of length 9 and rate $R = 1.89$ bits/symbol results, with the same minimum symbol and product distances as Λ_2 , but reduced bandwidth efficiency and slightly higher decoding complexity (a block length of 9).

Computer simulation results for Λ_1 (EEP) and Λ_2 (UEP) are shown in Figure 3. The results were obtained using a *uniform 8-PSK signal set* with natural labeling and single-stage maximum likelihood soft-decision decoding using the Viterbi algorithm. The increase in coding gain for the most important message part is very impressive. At a bit error rate (BER) of 10^{-3} , the coding gain in the third stage is at least 13 dB for Λ_2 , compared to about 8.5 dB for Λ_1 . Note that for the conventional multilevel code Λ_1 , the largest coding gain at a BER of 10^{-3} occurs in the 4 bits encoded by the first stage (Pe1). This coding gain is about 11.5 dB compared to 14 dB in the third encoding stage (the 4 MSB encoded by the LUEP code) for Λ_2 . In addition, the overall coding gain for the proposed construction at a BER of 10^{-3} is about 2 dB larger than for the conventional multilevel code.

4. A LENGTH-32 MULTILEVEL CODE FOR UEP OVER RAYLEIGH FADING CHANNELS

Let C_1 , C_2 and C_3 be (32, 16, 8), (32, 26, 4) and (32, 26, 4) Reed-Muller (RM) codes, respectively. The multilevel construction yields a block modulation code Λ_4 of length 32, rate $R = 2.125$ bits/symbol,

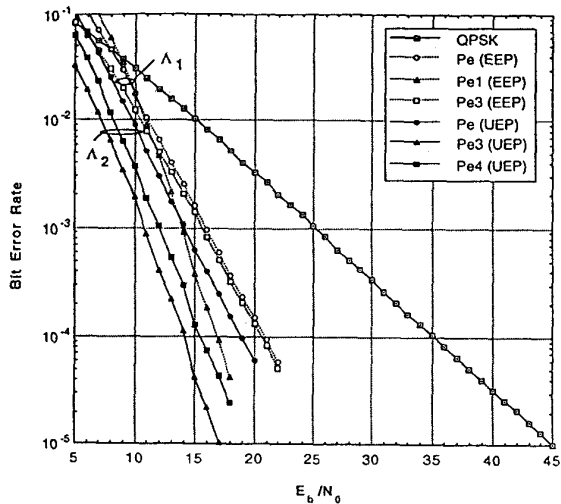

FIGURE 3: Simulation results for Λ_1 (EEP) and Λ_2 (UEP). (Pe: Overall bit error rate (BER), Pe1: BER in stage 1, Pe3: BER in stage 3 for the MSB, Pe4: BER in stage 3 for the LSB).

minimum symbol distance $\delta_H = 4$ and minimum product distance $\Delta_p^2 = 16$. This code was analyzed in [9] and shown to achieve high performance over a Rayleigh fading channel.

Let C_1 and C_2 be as above and let C_3 be a UEP(32,22) code with separation vector $\bar{s} = (6, 4)$ for the message space $\{0, 1\}^7 \times \{0, 1\}^{15}$. This UEP(32,22) code is obtained from combining an extended (16,7,6) BCH code and a (16,15,2) RM code using the $|u|u+v|$ construction [4]. The result is a block modulation code Λ_5 of length 32, rate $R = 2$ bits/symbol, $\delta_H = 4$ and $\Delta_p^2 = 16$, that provides coded sequences in correspondence to 10.94% of the information (the 7 MSB encoded by C_3) with symbol and product distances of 6 and 4096, respectively. This results in enhanced UEP capabilities and higher overall error performance with respect to Λ_4 , with the same bandwidth efficiency as uncoded QPSK modulation.

Λ_5 is compared with BCM for UEP using conventional linear block codes as follows: To obtain the same error protection capabilities as the UEP code C_3 used by Λ_4 , the time-sharing of (16,7,6) and (21,15,4) linear codes, resulting in a UEP(37,22) code, denoted $|(16,7,6)|(21,15,4)|$, may be used. Let C_1 be a (37,22,8) linear code from the table

of best linear codes [11], C_2 be a (37,30,4) linear code (a shortened Hamming code), and C_3 be the $|(16,7,6)|(21,15,4)|$ code. The multilevel construction results in a modulation code Λ_6 of length 37 and rate $R = 2$ bits/symbol, i.e., the same rate and error protection capabilities as Λ_5 . However, Λ_6 has higher decoding complexity (a block length of 37) than that of Λ_5 .

For MLSD using the Viterbi algorithm, the decoding complexity (as defined in Section 2) of Λ_4 is $2^9 \times 2^4 \times 2^4 = 2^{17}$. For Λ_5 the binary LUEP code used in the third stage of the multilevel construction introduces additional decoding complexity. In the third stage, a minimal trellis diagram for the UEP(32,22) code requires 2^7 states, as opposed to 2^4 for the (32,26,4) RM code used in Λ_4 . The decoding complexity of the proposed BCM for UEP of length 32 is thus roughly eight times that of conventional BCM (The increased decoding complexity of the UEP code in the third stage). However, with the use of *multistage decoding* the decoding complexity of Λ_4 is $2^9 + 2^4 + 2^4 = 512 + 32 = 544$, compared to $2^9 + 2^4 + 2^7 = 512 + 16 + 128 = 656$ of Λ_5 . As mentioned in the previous section, the same reduction in coding gain will be experienced in the first two decoding stages of both Λ_4 and Λ_5 , while the use of a UEP code in the third stage of Λ_5 provides UEP capabilities. The proposed code achieves increased error performance and UEP capabilities at the expense of a 20% increase in decoding complexity, using multistage decoding, with respect to the multilevel code using conventional linear block codes.

5. CONCLUSIONS

It has been shown that the use of a binary LUEP code as component code in the multilevel construction produces enhanced UEP capabilities and increased error performance, at a modest reduction in bandwidth efficiency and a relatively small increase in decoding complexity. The proposed constructions offer a good trade-off between bandwidth efficiency, error performance and decoding complexity, which would otherwise be impossible to achieve using conventional linear block codes. Although in this paper the use of a binary LUEP as a component code in the multilevel construction is considered, it is possible to use two binary LUEP codes as component codes in the second and third encoding stages, if bandwidth efficiency and decoding complexity constraints allow it.

Finally, it should be noted that in this research work a *uniform* 8-PSK signal set is used, as opposed to previously proposed BCM [5] which use nonuniform 8-PSK signal constellations. The improvement in error performance for part of the information symbols (UEP) is achieved here by increasing the Hamming distance between codewords in one or more of the encoding levels, through the use of LUEP codes, as opposed to increasing the product distance directly in the signal space as is the case in a nonuniform signal set. One problem with the use of nonuniform signal sets is that the increase in error performance for the most important information bits is usually obtained at the expense of a (sometimes considerable) performance degradation for other information parts. In this paper, multilevel constructions of block coded 8-PSK modulation for fading channels have been presented that achieve excellent error performance with no degradation of any information part.

Future research activities include the generalization of the examples presented in this paper to families of block coded 8-PSK modulations with unequal error protection capabilities.
